

ICRI resolution on coral reefs & climate change

This resolution was approved by the ICRI members at the the ICRI General Meeting held in Tokyo, Japan (April 23rd - 24th, 2007).

In light of the IPCC Fourth Assessment Reports "Climate Change 2007: The Physical Science Basis, Summary for Policy Makers" and "Climate Change 2007: Impacts Adaptation and Vulnerability, Summary for Policy Makers";

Noting with concern the projected impacts on coral reefs, including coral bleaching, increased intensity of tropical cyclones, and ocean acidification, all of which negatively impact the health of coral reef ecosystems;

Noting further the statement on Coral Reefs and Climate Change adopted by 350 coral reef managers and scientists who participated in the Third International Tropical Marine Ecosystem Management Symposium (see Annex);

The International Coral Reef Initiative:

Recognizes that climate change poses a significant threat to the condition of coral reef ecosystems globally and the wellbeing of 100s of millions of people that rely on reefs for subsistence and livelihoods.

Recognizes that the future condition of coral reefs will be significantly influenced by the rate and severity of climate change and that actions to mitigate climate change are important to maintaining reef values.

Recognizes that meaningful actions can be taken to support coral reef resilience, such as those outlined in A Reef Manager's Guide to Coral Bleaching and the Reef Resilience Toolkit.

Calls on its members to:

1) **Support actions to improve coral reef resilience to climate change** by maintaining or enhancing good water quality, healthy coral cover, and the full range of biodiversity, including good herbivore (plant-eating) populations, and by working with local stakeholders to protect biological diversity and reduce direct stresses;

- 2) **Support research** to improve the understanding of factors that promote resilience in coral reefs and their application in management;
- 3) **Support the development of sustainable livelihoods** that may reduce vulnerability to climate change among coastal populations and strengthen ecosystem resilience;
- 4) **Enhance public awareness** of the impacts of climate change on coral reefs.

Annex: ITMEMS 3 statement on Coral reefs and climate change

There is no longer any doubt that the earth's climate is changing, causing rapidly warming seas and ocean acidification. Warming seas are causing increased mass coral bleaching and mortality, with little evidence that corals and their symbionts can evolve fast enough to keep pace. In addition to these impacts, there is now strong evidence that acidifying seas are reducing calcification rates. Other consequences, such as rapid sea level rise and increased frequency and intensity of tropical storms, and impacts on other organisms and ecosystems, further emphasize the urgent need to limit the rate and extent of global climate change.

Projected changes in temperature and ocean acidity pose significant problems for reef-building corals. As reef-building corals build the habitat and ecosystem in which many tens of thousands of organisms live, these changes in global climate are causing major changes to the biodiversity of the ocean. Because coral reefs directly support at least 100 million people and multi-billion dollar industries, like tourism and fisheries, these impacts will cause significant socio-economic impacts and threaten food security in developing nations.

Two strategies must be implemented to mitigate the impacts of climate change to coral reefs. The first is to limit climate change. The second is to build the resilience of tropical marine ecosystems and communities to maximize their ability to resist and recover from impacts such as mass coral bleaching. Within this context our ability to effectively reduce other stressors will determine the future of coral reefs.

The actions required to support reef resilience to climate change are:

1. Limit climate change to ensure that further increases in sea temperature are limited to 2°C above pre-industrial levels and ocean carbonate ion concentrations do not fall below 200 $\mu\text{mol kg}^{-1}$.
2. Recognise that mass coral bleaching will have similar social and economic consequences as other environmental disasters such as oil spills and droughts and will require similar responses.

3. Facilitate and finance actions to increase resilience of coral reef social-ecological systems, particularly through marine management area networks comprising adequate areas of coral reefs and associated habitats in non-extraction zones, protection of water quality and herbivore populations, and adaptive governance.
4. Facilitate and finance assessments of risk and vulnerability of coral reefs to climate change.
5. Facilitate and finance the development and implementation of coral bleaching response programs, including contingency funding.
6. Create incentives for development of partnerships for adaptation.
7. Increase investments in targeted messages to accelerate adaptation to climate change.
8. Invest in village-to-global education and communication for climate adaptation that will integrate traditional and scientific knowledge into implementation of adaptation strategies for coral reefs around the world.
